# Identity Blockchain - Proof of Identity

Albert Vučinović, University North Miroslav Jerković, University of Zagreb

July 23, 2022

### Abstract

Identity Blockchain uses state-certified electronic identities (eIDs) to create blockchain identities and a consensus protocol called Proof of Identity (PoI). PoI is "green" and enables many applications that are impossible to implement without verified identity on the blockchain, e.g., direct democracy and universal basic income, encrypted messaging, etc. Identity Blockchain preserves identity anonymity by using zk-SNARKs and an anonymization protocol for identity onboarding.

## 1 Introduction

TODO

### 2 Notation

$(K,K^{-1})$	Pair of public key $K$ and the corresponding private key $K^{-1}$
K(value)	String $value$ encrypted with a public key $K$
$K^{-1}(value)$	String value encrypted with a private key $K^{-1}$
H	zk-SNARK-friendly hash function
Nin	Unique state-issued personal $National\ Identification\ Number$
CA	Certificate Authority
eID	Electronic identification document
$K_{ID}$	CA-certified public key of eID
$K_P$	Person key, unique public key used to access <i>Identity Blockchain</i>

Sometimes we write K for  $(K, K^{-1})$ .

# 3 Registering $K_{ID}$

Register  $K_{ID}$  on *Identity Blockchain* by calling

```
register K_{ID}(H(Nin), K_{ID}^{-1}("register K_{ID}"), proof Nin Owns Kid).
```

### Pseudo-solidity code

```
mapping(uint256 => uint256) public ninKidUsed;
1
     mapping(uint256 => bool) public kidInvalid;
2
3
4
     function registerKid(
       uint256 hNin, // hNin = H(Nin)
5
       uint256 vKid, // vKid = KidPrivate("registerKid")
6
       bytes proofNinOwnsKid
7
8
     ) public {
       uint256 previousKey = ninKidUsed[hNin];
9
       if (previousKey == vKid) return; // already registered
10
11
       bool isOwner = zksnarkverify(VK, [hNin, vKid],
           proofNinOwnsKid); // VK = verification key
12
       if (isOwner && !kidInvalid[vKid]) {
13
          if (previousKey != 0) kidInvalid[previousKey] = true;
14
         ninKidUsed[hNin] = vKid;
15
16
```

### Pseudo-circom code

Using https://github.com/zkp-application/circom-rsa-verify for now, MIT license. Which probably doesn't work, we should check (sha256?).

The next line is used on a file of shape:

```
—BEGIN PUBLIC KEY—

...
—END PUBLIC KEY—
—BEGIN CERTIFICATE—

...
—END CERTIFICATE—

We assume:
modulus = Subject Modulus
exp = Subject Exponent
openssl x509 -in Identification.pem -text -noout
```

Statements we need to check:

- CA is an accepted CA by *Identity Blockchain* 
  - A set representation exists on blockchain which contains CA public keys (CA-public-keys).
  - Verify inclusion of the CA in cert in CA-public-keys.
  - A set representation exists on blockchain which has all the revoked CA public keys (Revoked-CA-public-keys).

- Verify exclusion of the CA in cert from Revoked-CA-public-keys.
- Verify CA validity with respect to time (maybe blockchain)
- Cert CA signed
  - the Kid
  - x509 Subject that contains Nin in the right place in the subject
  - verify Validity of x509 cert with respect to time
- Kid is not on revoked certs list by CA (blockchain hosted list)
- Kid decrypts vKid into clear text "registerKid".

```

### Features

### Sybil resistance

A Person is prevented from registering more than one  $K_P$ , e.g. by using different identification documents issued for the same Nin.

#### Fix for the loss of eID

A Person who has lost a previously registered  $K_{ID}$ , e.g. due to loss of eID, can overwrite it by registering a new  $K_{ID}$ .

### Identity theft damage control

If a Person overwrites the previous  $K_{ID}$  with a new one, the identity Thief loses access to services that verify the entire identity chain.

### $\underline{\text{Remarks}}$

- i) An entity that knows  $K_{ID}$ , e.g. the CA who certified the corresponding eID, can know that the Person has registered  $K_{ID}$  on *Identity Blockchain*.
- ii) Reasoning for the choice of arguments: if  $H(Nin, K_{ID}^{-1}("registerK_{ID}"))$  was used as an argument, then TODO. On the other hand, the choice of arguments Nin and  $K_{ID}^{-1}("registerK_{ID}")$  would TODO.

# 4 Registering $K_P$

Register  $K_P$  on *Identity Blockchain* by calling

```
register K_P(NinK_{ID}, NinK_{ID}K_P, proof),
```

where:

```
NinK_{ID} = H(Nin, K_{ID}^{-1}("registerK_P"))
NinK_{ID}K_P = H(Nin, K_{ID}^{-1}("registerK_P"), K_P^{-1}("registerK_P")).
```

### Pseudo-solidity code

```
mapping(uint256 => uint256) public ninKidKpUsed;
 1
      mapping(uint256 => bool) public kpInvalid;
2
      mapping(uint256 => uint256) public ninKidKpLastConfirmed;
3
4
 5
      function registerKp(
6
        uint256 ninKid,
        uint256 ninKidKp
 7
8
        bytes proof
9
      ) public {
10
        uint256 previousKey = ninKidKpUsed[ninKid];
        if (previousKey == ninKid) return; // already registered
bool ok = zksnarkverify(VK, [ninKid, ninKidKp], proof); //
11
12
             VK = verification key
13
        if (ok && !kpInvalid[ninKidKp]) {
          if (previousKey != 0) kpInvalid[previousKey] = true;
14
15
          ninKidKpUsed[ninKid] = ninKidKp;
          ninKidKpLastConfirmed[ninKid] = block.number;
16
17
      }
18
```

### Features

### Sybil resistance

 $K_P$  is a unique public key bound to the Person on the *Identity Blockchain*. By design, the Person cannot have two valid  $K_P$  keys at the same time. TODO: Explanation/proof.

#### Anonimity

No one who has a database with all public keys  $K_{ID}$  or/and public keys  $K_P$  can tell, from the function call, which Nin,  $K_{ID}$  or  $K_P$  was used. This is true under the assumption that CA, which certified the eID, does not have access to  $K_{ID}^{-1}$ , i.e. that  $K_{ID}$  was securely generated on the eID.

TODO: Explanation/proof.

### Remarks

i) Reasoning behind the choice of arguments: TODO

## 6 Problems

- **P1** The rate of addition of identities, the problems of frequent changes of Merkle Tree Roots, and how long it takes to generate zkp proof, and block generation time.
- **P2** The Thief stole  $K_{ID}^{-1}$  before we registered on *Identity Blockchain* and then registered  $K_{ID}$  and  $K_P$ .
- **P3** The Thief stole  $K_{ID}^{-1}$  after we registered on *Identity Blockchain*.
- P4 Trying to use unregistered Key.
- **P5** Trying to register the same *Nin* with multiple Keys (e.g. two physical ids).
- **P6** Using  $K_P$  without checking the whole  $CA \to K_{ID} \to K_P$  chain.
  - i) Using  $K_P$  to register as a mining key.
  - ii) Invalidating  $K_P$ .
  - iii) Using new  $K_P$  as a mining key.

#### Solution

Look at the solution to ??.

The Mining Registry can accept new  $K_P$  after an expiration period (which can be e.g. one day).

**P7** A combination of ?? and ??. The Thief steals  $K_{ID}$ , registers  $K_P$  and registers  $K_P$  for mining. The problem is bigger, because we can't invalidate  $K_P$  if we don't know which  $K_P$  it is.

### Solution

We make  $K_P$  renewable. We write the last block number it was renewed on to the *Identity Blockchain*. Mining Registry can choose to accept  $K_P$ that is not older than some time period (for the Registry a good period would seem to be one day). When paying the miners, the Registry also requires proof of  $K_P$ .

**P8** Only  $K_P$  is compromised.
